

## **The Legislator's Role in Criminal Deterrence Policy**

Determinate sentencing became the predominate sentencing philosophy in the mid 1970s. Since then the literature on deterrence theory and criminal justice policy in general has paid much attention to the role legislators play in deterrence theory. It often lays much of the blame for any inefficiency and inefficacy of the criminal justice system on the theory itself and especially on the politicians. Downplaying political involvement was the order of the day in the early 20<sup>th</sup> century with its emphasis on professionalism and criminological expertise (von Hirsch 1976; Tonry, 1992, 1996, 1999). As Erika Fairchild and Vincent Webb (1985, 16) put it: "The post-Progressive era is a consequence of emphasizing politics rather than progressive efforts to downgrade politics." The 1970s emphasized greater political involvement in the criminal justice system through the enactment of determinate sentencing laws and legislative authorization of new prisons.

Authors such as Wayne Welsh (1993), Joseph Davey (1998), Erika Fairchild and Vincent Webb (1985), and Alida Merlo and Peter Benekos (2000), to name but a few, have added their voices to this argument by stressing that for more than two decades now the academic community interested in criminological matters, that in the latter half of this century the legislature seemed to be the "best-equipped" to the problem of crime. Making the legislature the primary figure was intended to demonstrate a commitment on the part of the government (Windlesham 1998). Today, a generation later, the legislature is among the most relevant actors but little referred to in systematic studies on deterrence studies. Legislatures adopt laws that significantly influence the intake into prison as well as the length of stay. They also hold the power over the allocation of resources not only for the criminal justice system as a whole but for the individual organizations within the system." (Welsh 1993).

Scant systematic research has been conducted toward to further our understanding of legislative sentencing policy and of how the legislatures affect deterrence theory. There are, so far as I can determine, no empirical studies on the determinants of the criminal sentencing policies, that is, statutory maxima, and no data exists in any collected form until now (see Lynch 1988, 1993 for a qualitative approach to sentence severity and Bowers 1997, 1998; Bowers and Waltman 1993; and Marshall and Marshall 1997 for studies on judicially imposed severity studies). There is a lot of speculation and inconclusive cross-jurisdictional comparisons of sentence severity, but the severity he refers to is judicially imposed sentence severity and not sentence severity as it is adopted at the law-making stage. Statutory severity is important in and of itself. The legislative role is to provide the public with which to judge the seriousness of a given crime. The extent of their role in deterrence theory and practice is, however, much more critical. Legislatures set the rules. They first establish the threat of punishment; therefore they have the first say in what the expected cost of punishment should look like. By deciding the amount of resources to allocate to the criminal justice agencies, they ultimately influence the certainty and severity of punishment and, ultimately, the success of deterrence strategies.

### **The Role of the Legislature in Criminal Policymaking**

Why is that determinate sentencing has left criminal justice scholars unsatisfied, just as they once were with the indeterminate sentencing scheme? The “politics as symbolism” literature (Lasswell 1930; Edelman 1971, 1964; Oppenheimer 1974; Elder and Cobb 1983; Beckett 1998) provides one answer. In essence this literature, as applied to criminal policymaking, i.e. “law and order politics”, suggests that politicizing the issue of crime has made the production of rational criminal policies very difficult; some would say impossible (Elder and Cobb 1983; Tonry 1999; Merlo and Benekos 2000). Candidates avoid serious

discussion of both the complex nature of crime and the commitment of time and resources necessary to confront this social problem [crime] adequately...the momentum of get-tough, punitive politics seems resistant to rational analysis of the causes of crime and consequences of retributive punishment. ... As with the get-tough ideology and policies of the 1980s and 1990s, the post-modern penology is likely to generate its own dysfunctions.”(Merlo and Benekos 2000 12,107).

If politicians are, “single-minded seekers of reelection” as David Mayhew (1974) suggested and are only involved in “lawmaking, pork barrelling, and casework” (Fiorina 1975), they are concerned with the public interest insofar as they can attract and secure the vote. This is likely to undermine rational sentencing policymaking. Elder and Cobb (1983, 1-2) claimed that politics is neither rational nor irrational but rather *arational*, meaning that while politics may have rational and irrational elements to it, it largely comes down to politicians working in a “loosely structured process of interpreting fragmentary information and ambiguous cues in the light of prior expectations and changing, uncertain, or conflicting personal preferences.”

In the late 1970s Michael Hayes, building on theory by Robert Dahl and Charles Lindblom (1953); Theodore Lowi (1964; 1972), Morris Fiorina (1975), David Mayhew (1974), and Robert Salisbury and John Heinz (1970) developed a theory of transactional costs of lobbying. In doing so, he discusses his take on Lowi and Edelman’s typology of policies. Of interest here is his argument on regulatory policy. Salisbury and Heinz (1970, 40) posited that “there is a fundamental distinction to be made between decisions that allocate tangible benefits directly to persons or groups...and decisions which establish rules or structures of authority to guide future allocations.” They go on to argue their viewpoint on how the politics of regulations is conditional upon the decisionmaking structure and the demand pattern for a given policy. By decisionmaking structure, Salisbury and Heinz mean the degree of integration of the decisional system. By the pattern of demand, these authors refer to the degree of unity among the individuals or groups, and not merely their interests, when pressing for a given policy.

Depending on whether the degree of integration in the system and in the demand pattern are fragmented or integrated, legislators will behave one way or another; that is, they will produce one type of policy as opposed to another.

This relationship among the decisional structure, demand pattern, and the cost of the policy to the legislators is what inspired Hayes to take Salisbury and Heinz's theory a step further and postulate that legislators will likely pass on making decisions when the electoral costs to them of deciding one way or another are excessively high *and* when demand is sufficiently fragmented to allow them the needed room to maneuver. When it comes to criminal justice policy, the criminal justice system is permeated with institutional fragmentation as I discussed in the Chapter One. "Constituency problems are the second peculiarity of the criminal justice agencies [the first one is institutional fragmentation] that distinguish them from conventional policy-making agencies in American government." (Nagel et al. 1983, 8). As for costs, crime is undoubtedly a controversial issue, one that can make or break an election campaign—that means it is costly. Finally in regard to the demand pattern, it may be arguably consensual, but it is quite diffuse (Niskanen 1971; Benson et al. 1995; Nagel et al 1983; Elling 1996; Lynch 2000). "There is virtually no organized and effective political opposition to spending more money on police and prisons...There are no interest groups which can effectively support lower levels of spending on law enforcement and prisons." (Lynch 2000, 5-6). Salisbury and Heinz are careful to point out that consensual demand does not only refer to unity of interests among interested parties; the unity of the actors themselves is essential to their theory. "Criminals don't have unions and political action committees to lobby against higher spending." (Lynch 2000, 6). "Criminal justice shares with poverty policy the fact that organized constituencies that attempt to influence policymaking are not the clients of the system..., but rather the professionals who deal with them...Thus, it is the self-interest of professionals that become the focus of bargaining and compromise in policymaking."(Nagel et al. 1983, 11).

What happens is what Hayes calls “issue movement.” That is, legislators will produce regulatory policy and defer the real decisionmaking process elsewhere. Since “A theory of policy formulation must, if it is to be comprehensive, account for policies made by all kinds of governmental agencies...” (Salisbury and Heinz 1970, 49), the other actors in the system would have to deal with the legislative regulatory policy. In the criminal justice system, where would legislators delegate or in lay terms, where would they “pass the buck”? To the administrative (law enforcement and prosecution and corrections) and the judiciary. The end result is what Lowi (1969) calls “policies-without-law”. From an applied criminal justice policy viewpoint, these would be criminal policies where policymakers will decide on statutory severity, for instance, in a way that will satisfy the public’s and the various interest groups’ demand for harsher punishment in a sufficiently abstract or vague manner. They will do this just enough to look as if they are acting on the issues (Lasswell 1930; Tullock 1967; von Hirsch 1976; Hayes 1978,1981), but in reality all they are doing are granting those who will have to execute the policy or make the real decisions with a broad discretionary powers.

“The number of statutes which pass the legislature, or the number of decrees which are handed down by the executive, but which change nothing in the permanent practices of society, is rough index of the role of magic in politics... .” (Lasswell 1930, 195).

This is the core of the “political symbolism” criticism of the legislative role in the making sentencing policy.

### ***Hypotheses***

The question of interest here is why some states or nations have more severe sentences than others. Why do jurisdictions differ in the level of severity? What are the key determinants of statutory severity in a given state or nation? To address these questions, I test four key

hypotheses. As with any other policy, sentencing policy should constitute a reflection of: 1) the need for it; in this case that need originates from the crime rate; 2) the will or desire for it; here, that desire comes from the public and the policymakers themselves; and 3) the availability of resources.

Establishing the deterrent threat of punishment is influenced by a state's need to reduce the crime rate. Policymakers in states with higher crime rates need to impose more severe deterrent penalties (the deterrent or need hypothesis). Elected public policymakers are also expected to be responsive to the public's preferences in regard to policy choices or run the risk of being rejected in the next election period. One can thus expect public opinion to influence policymakers' decision in establishing a credible sentencing policy. This is the "democracy-at-work" thesis (Beckett 1998). Public opinion can be more or less conservative or more or less liberal. We know from electoral theory that voters choose representatives that share their values and/or views on political issues. And we know that it is the role of the parties, among others, to aggregate public interests and translate public preference into policy. Those jurisdictions with a more conservative electorate would be inclined to adopt more severe deterrent threats and those with a more liberal electorate would adopt more lenient or less severe sentences.

The potential that a jurisdiction will have to raise the public funds necessary to build more prisons should affect policymakers' decision as to whether they should establish a greater or lesser severity of the deterrent threat. Some authors have argued that this may not be the case. The fact that other actors in the criminal justice system such as the courts and correctional agencies are more dependent on their environment than the legislature leaves the legislators with a greater margin to maneuver. Jurisdictions with more prison availability and great tax or revenue raising capacity are more likely to establish greater statutory penalties (the resource constraint or overcrowding effect hypothesis).

In addition to a direct effect, prison capacity could also mediate the political will to establish a specific penalty. This means that the relationship between sentence severity and public opinion would be conditional upon the availability of prison space and the capacity of a state to provide more space so that sentences in a very conservative but less affluent state may be more lenient than in an equally conservative but more affluent state. Also, jurisdictions with a higher crime rate but overcrowded prisons may be more lenient than otherwise expected. Prison space availability and/or greater tax or revenue raising capacity conditions the political will and need for establishing more severe statutory penalties.

### **Research Design and Data**

Tables 1 and 2 list the statutory maxima allowable in years for six different crimes in 48 U.S. States (Alaska and Hawaii are excluded due to missing data on some key explanatory variables) and in 16 Western European nations. These maxima represent the set of dependent variables under analysis. The crimes covered are: robbery, burglary, and larceny in the U.S. and rape, robbery, and theft in Europe.<sup>1</sup>

[Tables 1 and 2 about here]

Tables 3 and 4 present the descriptive statistics of the variables employed for the U.S. and Western Europe, respectively. These numbers tell that the deterrent threat as measured by the harshest allowable penalty for committing a particular crime is on average substantially higher for violent crimes than for property crimes, in both the U.S. and Europe.

[Tables 3 and 4 about here]

When comparing Tables 3 and 4, I can see that the U.S. is potentially harsher than the Western European nations under analysis. The U.S. also provides more prison space as there are comparably more crimes per 100,000 persons. In the U.S., robbery is punishable by death,

whereas in Western Europe, life is the maximum penalty for this crime. Life is also the maximum penalty for any kind of theft, burglary or larceny in both the U.S. and Western Europe. In general, though, the typical statutory penalties are a bit higher for the same crimes in the U.S. than in Europe. In the U.S., a criminal committing a first-time aggravated robbery could typically, on average, face up to about 260 months in prison; as many as 190 months on average for aggravated burglary and about a third of this, 64 months, for aggravated larceny. There were on average in 1995 about 153 robberies per 100,000 persons, 925 burglaries for every 100,000 persons, and more than three times as many larcenies, 2,932 larcenies per 100,000 individuals. In Europe, a convicted criminal could get up to 242 months for a first-time, aggravated rape, just about what criminal could face in the U.S. for robbery; about 213 months for robbery; and about 123 months for theft. During the same year, 1995, there were on average eight rapes for every 100,000 persons, nine times as many robberies or 76 for every 100,000 persons, and over 400 times as many theft; that is almost 3,800 thefts per 100,000 persons.

European prison capacity was in 1995 considerably smaller than in the U.S.—78 cells per 100,000 persons, on average, in Europe and in the U.S. almost four times that, 300 beds for every 100,000 persons, assuming one bed for every cell.<sup>ii</sup> We know that at least in the U.S. this is a big assumption as double-bunking is widespread.

On a scale from 1-5, government opinion in the U.S. is typically Center-Right around 3.5, where a higher score indicates a more liberal attitude. Electoral opinion is conservative and ranges from .2 to 28 with a mean of 14.3. It is measured as the conservative balance, calculated by subtracting the percentage of those individuals identifying themselves as liberals from the percentage of those identifying themselves with the conservatives. Differently, European government opinion is Center-Left, -6, and the median voter's left-right position, ranging from -11 to about 21, is typically Center-Right around 6.

## The Model and Findings

If one were to model the determinants of statutory severity for a given crime, such a model could look like the following:

$$\begin{aligned} \text{SentenceSeverity} = & \beta_0 + \beta_1 \text{CrimeRate} + \beta_2 \text{GovtOpin} + \beta_3 \text{ElectOpin} + \beta_4 \text{PrisonCap} + \beta_5 \\ & \text{TaxCap} / \text{CorrectionsRev} / \text{StateGDP} + \beta_6 (\text{TaxCap} / \text{CorrectionsRev} / \text{StateGDP} \\ & * \text{GovtOpin}) + \beta_7 (\text{CrimeRate} * \text{PrisonCap}) + \beta_7 \text{OpportunityCosts}, \end{aligned}$$

*SentenceSeverity* measures the maximal threat of punishment in months of imprisonment that rational potential criminal may expect to face when breaking the law. *CrimeRate* is the number of offenses per 100,000 persons. *GovtOpin* is the government's opinion measured as the level of conservatism/liberalism of the government; *ElectOpin* is the electorate's opinion measured as the level of conservatism/liberalism or Right/Left; *PrisonCap* refers to the number of available beds or cells for every 100,000 persons; *TaxCap* represents another source of resource constraint on policymakers. It is measured as either the per capita tax revenue or tax revenue as a percentage of GDP. *CorrectionsRev* and *StateGDP*, measured in per capita millions and billions of dollars, respectively, are alternative resource constraints in the case of the U.S.; *Opportunity Costs* refer to major social expenditures other than criminal justice expenditures that policymakers must also make. Specifically, they refer to public welfare and education expenditures in the U.S. case and health and education expenditures in Europe.

There are several concerns with a model such as this one. For one, there is the potential reciprocal relationship between statutory maxima and the crime rate. Second, one could also make the case of a simultaneous relationship between statutory severity and the opinion variables. Of course 2SLS and 3SLS would be a solution to these concerns, however, as I will show, this would needlessly occupy time and space. The OLS results, reported below, are

sufficient to suggest what the data already suggest—that there is little to lead one to expect that legislatures to arrive at a rationally-derived deterrent penalty. States like Alabama, Maryland, Rhode Island, and Virginia have the same maximal penalty for burglary and larceny. One would hardly believe that with three times as many larcenies as there are burglaries, the legislatures of these States consciously meant to have burglars and thieves potentially receive the same penalty.

For the sake of a preliminary exploration of what the results of an OLS 1995 cross section-regression analysis of the above model can reveal, I present Appendix Tables 1 through 6; Tables Appendix 1-3 for the U.S. and Appendix Tables 4-6 for Western Europe.

The results show that not much is going on here to explain criminal sentencing in the legislatures. To begin with, not one of our models, for any of the crimes, in the U.S. and in Europe alike, show significant effects. Policymakers are simply not concerned with the need for the levels of severity. This means that we find no evidence that would imply that the crime rate is a driving force behind policymakers' decisionmaking. In general, the results are also indicative of null effects of resource constraints. In regard to opportunity cost effects on setting the statutory penalty, in all but one model and only in the European case. The more resources spent on health services, the less severe the statutory penalty for robbery and theft but not so for the more serious crime, rape.

Prison capacity is never statistically significant matter in arriving at statutory severity in either the U.S. and Europe, whether we are talking about direct or mediating effects. Political will is not mediated by the state's prison capacity. There is no evidence that the availability of prison space or beds makes a bit of difference to policymakers. The same is true of the state's capacity to back up the threat of punishment, at least in the U.S.. The state's tax capacity to sustain the threat through the resources that policymakers allocate to the organizations in the criminal justice system that put that threat into effect does not condition governmental opinion

in the U.S., but does so in the European case. Here, the tax capacity restricts or limits the positive effect of governmental opinion on statutory severity.

The results suggest that policymakers pay attention to what they think the level of severity should be limited only by the restriction of other social spending. Across the models presented, the more conservative the governments the greater the sentence policymakers are likely to adopt.<sup>iii</sup> Only in the case of larceny does electorate opinion reach statistical significance and in the expected direction, that is, a more conservative electorate has a positive influence on severity.

### **Implications for Rationality Expectations Theory in Criminal Policymaking**

While the evidence reported above is weak to nonexistent and potentially biased due to potentially reciprocal relationships between some the variables, it does suggest something important about the rationality or lack of it behind the sentences legislators adopt. We can say with some confidence that, aside from capital punishment, legislators are not too terribly concerned with variable punitive content for the sentencing policies they produce. Were they concerned, the level of severity they adopt, and tacitly approve by non-decisions thereafter, would be a reflection of the need for that level and the availability of resources. The notion of need here in this context is captured in the crime rates. As the results indicate, legislators do not appear to pay much attention to the crime rates nor to the level of prison capacity, which is that resource commonly agreed upon to be the most crucial resource limited in the criminal justice system. They are concerned with the desire for a given level of severity, as the “law and order” politics would lead us to expect. This means that they are simply concerned with conveying a tough approach, even if only symbolic, to the public. According to this body of literature, we should expect legislators to heed public opinion as much as possible. Political will has the primary role in criminal sentencing policy, at least where legislatures are concerned.

So if crime rates and resource capacity are not relevant factors in legislative sentence decisionmaking, the question becomes: How do legislators arrive at the level of severity for a given crime? And how does the level of severity for one crime differ from the level of severity of another, if they differ at all? Factor analysis, as I will show, allows one to decisively arrive at an answer to this question.

SS Stevens (1975, 259) asked “How well does society’s accumulated wisdom or lack thereof in legislating punishment accord with the judged gravity of offenses?” The just deserts rationale would suggest that severity should vary proportionately to the seriousness or harshness of a particular crime. “Fear of harm ought to be proportional not merely to the gravity of the harm but also to the probability of the event.” (Arnauld in *Logic*, 1662, cited in Bernstein 1999).

This would suggest that there should be something common at work—the association between the seriousness of the offence and the severity of the punishment—in all sentencing statutes. Therefore, the states or nations that have especially harsh or especially lenient penalties for one crime type would be expected to also have similarly harsh or lenient maxima for others. And states or nations would not adopt a greater severity of punishment threat for less serious crimes than for more serious crimes. This would make less serious crimes as punishable as more serious crimes and thus diminish the tradeoff effect between the deterrent cost of crimes (Becker 1968; Sollars et al 1994; Mendes 2000).

Looking to the data in Tables 1 and 2, the statutory maxima do not seem to have been adopted with the relationship between offense gravity and punishment severity. Too often the levels of severity among crimes do not differ much.

In many U.S. States, the maximal threat for rape is greater than that of voluntary manslaughter or on a par. In some states, for instance Pennsylvania and Montana, maximal threat of punishment is the same across the crimes of manslaughter, rape, robbery, and burglary. In other states, the lack of a relationship between the seriousness of the offense and the severity of

punishment is more glaring. In Oregon criminals can expect to get up to 20 years for robbery or burglary but only five for forcible rape. In New Hampshire the threat for rape is about half that of robbery or burglary. And in South Carolina, a convicted felon could get up to a life sentence for burglary but only 30 for robbery or rape. In Europe, Table 2 suggests that criminal severity threats are not as invariant as in the U.S.; however, in almost two thirds of the nations covered, the statutory severity of manslaughter is the same or about the same as that for theft. In England and Wales, a convicted person could get a greater punishment for theft—life—than for robbery—12 years. If criminals are rational beings as deterrence theory assumes, how do severity ceilings such as these factor into the calculation of the expected cost of punishment?

For more than 30 years, at least since the seminal work of Johan Thorsten Sellin and Marvin Wolfgang (1964), scholars have attempted to associate the judicial or imposed severity of punishment to the seriousness of the offense. Psychophysicists argued that “human observers can judge the ratio of two sensations, and they can do so with fair consistency” (Stevens 1975, 21). The Weber-Fechner Law of “just noticeable differences” states that various responses are proportionate to the intensity of stimulus. In a punishment setting, this psychophysical law tells us that there should be a relationship between culpability and penal punishment, whereby more serious crimes should correspond to stiffer penalties (von Hirsch 1976; Green and Allen 1981/82). This psychometric scaling or the measurement of sensation based on the estimation of the experimental perceived intensity of penal stimuli is referred to in the criminal literature as quantitatively-determined methods or consensual scaling. Other methods used to construct severity scales include subjective assignment and *ex-poste* judicially-derived scales (von Hirsch 1976; Sebba and Nathan 1984; Ostrom and Ostrom 1999). Sentencing scholars such as Maynard Erickson and Jack Gibbs (1979), Catherine Fitzmaurice and Kenneth Pease (1986), Pierre Tremblay (1988), and Leslie Sebba and Gad Nathan (1984) have argued that crime seriousness scales/severity of punishment scales have been successfully constructed when based on

stimulus-response relationships. The evidence of this literature largely suggests curvilinearity (Erickson and Gibbs 1979; McDavid and Stipak 1981/82; Sebba and Nathan 1984); that is, there is a declining marginal disutility of the severity of punishment. Linearity would imply that equal increases in the gravity of an offense would on average correspond to an equal increase in the severity of the punishment. As the severity of punishment increases, the perceived utility of increased punishment does not increase indefinitely, but rather its rate of increase decreases once the level of severity reaches a specific level.

These perceptual studies on the gradation or ordering of the severity of sentencing are based on information acquired from judges, inmates, and students (Buchner 1979; McDavid and Stipak 1981/82; Sebba and Nathan 1984; Tremblay 1986) but not from legislators. The results shown in this chapter suggest that perhaps there is a reason for this. A simple factor analysis of the statutory maxima, shown in Table 5, helps in arriving at a more confident conclusion regarding the rationality of legislative sentencing. According to the evidence thus far presented, I would expect to find that there is no guiding force common to all sentence maximum lengths. What these analyses tell us is that there is essentially no commonality among the severity in the legislative arena. There does not appear to be a functional relationship between the severity of punishment of a given offense and the seriousness of that offense. These sentences appear to be as if essentially arbitrary. The scores in Table 5 represent the eigenvalues of the factor analysis of the sentence maxima logged and unlogged for the U.S. and European.<sup>iv</sup> In the U.S., the sum of the initial eigenvalues—1.432 in the case of the logged sentences and 1.225 when the sentence maxima are not logged—does not reach half of the number of source variables, that is, the number of crimes for which we have statutory sentence data. There are six such variables in the case of the U.S. analysis and five in the case of the Europe. The one exception is the logged version of the European maximum sentences. An eigenvalue of 1.0 means that the factor analysis accounts for as much variance as one source variable; an eigenvalue of six in the U.S.

for instance would indicate that there is one common factor among all six variables so that it would be possible to reduce all six variables to a common factor. An eigenvalue of 1.2 or 1.4 indicates hardly any reduction toward a single factor (Uslaner 1976). These scores in other words reveal no commonality among the statutory maxima. Pure and simple.

[Table 5 about here]

A comparison of these factor analysis results to the results of another set of factor analyses of variables that are surely expected to have some common ground among would help stress this point. Such variables could be the crime rates of the respective offenses. Despite the complexity of explaining crime rates, judging from the factor analyses presented in columns three and four in Table 5, these do seem to have at least one common factor explaining them. The sum of the eigenvalues is about three or greater (out of seven source variables) in both the U.S. and Europe, regardless of whether they are logged or not.

What does this mean for sentence severity as the ultimate threat of punishment and essential component in the expected cost of punishment? More importantly, what does it mean for deterrence theory as it is applied to the criminal justice system as a rational deterrence strategy? From a policy perspective, which is the perspective relevant here, it simply means that legislatures are not approaching the criminal justice system from the rational mind set that stands behind deterrence theory. They are not concerned with the other actors' (in the criminal justice system) expectations, as the theory requires. "...if punishment is to play any role in criminal justice, existing penalties must be converted into a rational system." (Erickson and Gibbs 1979, 105). Hayes's argument of legislators "passing the buck" to the executive and the bureaucracy seems all too fitting for what appears to be going on here. "When the legislature determines sentencing ranges, it is operating at a level of abstraction far removed from individual case dispositions, or even the allocation of resources to courts and correctional agencies. At that level of abstraction the symbolic quality of the criminal sanction is of great

importance.” (Zimring 1976, 13). The statutes allow law enforcement and judicial actors enough latitude to carry out their function in the criminal justice system. The establishment of the threat of punishment in the legislative arena is not driven by any justifiable, objective need. So to answer Stevens’s question, legislated punishment does not accord very well with intuitive reasoning on the gravity of the offense.

## **Conclusion**

This paper investigated the determinants of the legislative threat of punishment for noncapital crimes. The story it tells is one of legislative uncoordination when it comes to setting the deterrent threat of punishment. This part of the criminal justice system is not concerned with setting rational component of deterrence, making them irresponsible from an applied policy view. Rather, legislative policymakers in delegating discretionary powers to the remaining actors of the criminal justice system they also delegate the potential for any rationality to them. Statutory severity of punishment is irresponsive to the need for more deterrent policies and the financial capacity to secure the threat of punishment.

The extent of the legislative involvement in the establishment of the potential threat of punishment appears all but blind to the crime rates, as well as prison capacity and tax capacity. In this way, the legislatures introduce the possibility of slippage in deterrence as a rational and comprehensive applied strategy. Rationality in applied deterrence strategies is absent in the legislative arena. Legislators leave rationality to the bureaucratic apparatus of the criminal justice system and the judiciary. Political will is *the* driving force behind legislative sentencing decisions, the only determining factor. The general finding is, as expected, more conservative or Right-leaning governments tend to adopt more severe threats of punishment.

There is no evidence that existing prison capacity makes a difference in deciding when

to level off statutory severity, but it would be interesting to see if, to what extent, and under what conditions legislative policymakers account for the level of severity they stipulate when adopting or tacitly approving the statutory maxima for a given crime. At some point politicians have to be held accountable even if that accountability lie in the budgetary allocation decisions they make. If policymakers are at all serious about deterrence strategies, then they have to empower the actors to whom they delegate decisionmaking power with tangible or material assets to make real decisions.

*Source:* U.S. State Penal or Criminal Codes (Cornell Myron Taylor Law Library).

\* New Hampshire repealed the death penalty in 2000.

*Notes:* 1.) These are penalties for a first-time, aggravated form of each offense. 2.) The length of sentence is in years. 3.) Murder penalty is for 1<sup>st</sup> degree murder. 4.) Rape is unarmed, forcible rape of a person that is not a minor but can be aggravated if causing serious injury. 5.) Robbery is unarmed, unaided robbery of a person < 60 years of age, but can be aggravated if causing serious injury. 6.) Burglary is unarmed breaking and entering of a dwelling that may or may not be occupied. 7.) The sentences for theft refer to offenses that exceed \$500.00 in value but do not exceed \$1,000.00 in value.

<b>Sum of Eigenvalues</b>	<b>2.951</b>	<b>3.114</b>	<b>3.279</b>	<b>3.263</b>

Extraction Method: Principal Axis; Rotation Method: Varimax

<sup>i</sup> As annotated in Tables 1 and 2, theft includes criminal acts that may be categorized as burglary and larceny according to U.S. standard definition of these crimes. For life and death sentences, we follow the Bureau of Justice Statistics National Reporting Program criteria of converting these sentences to 35, 40, or 60 years depending on whether we are talking about life with the possibility of parole, life without the possibility of parole, and death, respectively. They are the maximum allowable sentences for a first-time but aggravated form of each offense.

<sup>ii</sup> We know that at least in the U.S. this is a big assumption, given that double-bunking is widespread.

<sup>iii</sup> Since government opinion is coded so that a negative sign indicates a more conservative position, I multiplied the scale by -1 so that a unit increase in this opinion scale, leads to an increase in the number of months of the threat of punishment. Only in the case of larceny does electorate opinion reach statistical significance and in the expected direction, that is, a more conservative electorate has a positive influence on severity.

---

<sup>iv</sup> There are two reasons for factor analyzing the logged values, one is statistical and the other is theoretical. The first is provided in the literature on sentence severity scaling: the declining marginal utility of the severity of punishment. Thus, logging the variables allows us model the function more adequately. Tufte (1974, 108) explains a second reason. Given the large variance among the sentences, the potential skewness in the distribution of the source variables is great. He explains that logging, for instance, these sentence maxima “spreads out the clustered values” and “pulls otherwise outlying values toward the middle of the distribution”.

We discuss how institutional and policymaking characteristics may affect the EU's ongoing effort to enhance security and safety for the inhabitants of European states. Five Dimensions of Bureaucratic Politics "Bureaucratic Restraint" "Bureaucratic Confrontation".

Figures - uploaded by Mark Rhinard. Politics and Policymaking in the EU. Mark Rhinard—Arjen Boin. Swedish Institute of International Affairs, mark.rhinard@ui.se. Many actors. have a voice in decisions, which can explain why legislative agreement is usually. preceded by hard-fought negotiations and long delays: the average time span. between proposal and agreement in the Council is 16 months (Falkner et al., 2005). In the area of homeland security, the fairly permeable nature of EU. For us to judge a community as "democratic", we suggest here that all five features must be found together, as a kind of "syndrome" to apply to any political system. [1]. The paper considers current reform initiatives in the APS and examines the implications of citizen-centric ideals for the processes and structures of government agencies, for the attributes, skill sets and dispositions of public servants, and for the culture of the APS. It considers other jurisdictions' experiences with citizen-focussed approaches, and takes a closer look at the notion of "co-production" as an exemplary exercise in citizen engagement in policymaking and the design and delivery of services. Bills pass through the legislative process concurrently, meaning they pass through the House of Representatives and the Senate at the same time. Despite this concurrent passage there are some differences in the process between the House and the Senate.

1. First Reading. The bill is introduced in either chamber by a Representative or Senator. They will now become the sponsor of the bill. In the first reading the name of the bill is read out and a quick vote is taken to see if it will proceed. This is a mere formality and most bills pass this stage.
2. The Committee Stage. Political scientists know remarkably little about the extent to which legislatures are able to influence policymaking in parliamentary democracies. In this article, we focus on the influence of legislative institutions in periods of coalition government. We show that multiparty governments are plagued by "agency" problems created by delegation to cabinet ministers that increase in severity on issues that divide the coalition. We also argue that the process of legislative review presents an

CONTINUE READING. View on Cambridge Press. The legislative process in the United States is how a bill introduced in the United States Congress becomes a law. This page overviews this process so readers have a greater understanding of the process that intellectual property- and other Internet-based legislation must go through in order to become a United States law. Congress is the legislative branch of the United States government. It has two branches, the United States House of Representatives and the United States Senate . The House has 435
